

Project ReadMe

• Team Name:	RudyRudyRudy		
• Team members names and netid:	Katherine Comito - kcomito Julia Lizak - jlizak		
• Overall project attempted, with sub-projects:	Hamiltonian Paths/Cycles - The Traveling Salesman Problem Brute Force and Backtracking		
• Overall success of the project: Backtracking: The backtracking was fully successful. The program has a working depth-first search backtracking that finds the Hamiltonian cycles on weighted graphs. It is able to handle graphs with and without the cycles, reads the graph csv, and measures the runtime of each graph. Brute Force: Brute force is complete and successful. The program tries every possible ordering of vertices. It checks whether each ordering forms a Hamiltonian cycle or not. I was able to handle graphs with AND without cycles, read the csv test files, all while recording the timing results for each file. Also added some fun ways to visualize the graphs once they were all working correctly. Works cited in the readme file on github.			
• Approximate total time (in hours) to complete: Backtracking: 10 hours Brute Force: 9 hours			
• Link to GitHub repository:	https://github.com/julializak/toc-project1-rudy.git		
• List of included files (if you have many files of a certain types, such as test files of different sizes, list just the folder): (Add more rows as necessary)	<table border="1"><tr><td>File/Folder Name: <code>code</code></td><td>File Contents and Use: python files for all the processing of backtracking and brute force. Additional python files for plotting and visualizing the results</td></tr></table>	File/Folder Name: <code>code</code>	File Contents and Use: python files for all the processing of backtracking and brute force. Additional python files for plotting and visualizing the results
File/Folder Name: <code>code</code>	File Contents and Use: python files for all the processing of backtracking and brute force. Additional python files for plotting and visualizing the results		

- Code Files:
- backtracking_RudyRudyRudy.py
 - graph_reader_RudyRudyRudy.py
 - plot_cycle_rudyrudyrudy.py
 - run_timing_rudyrudyrudy.py
 - timing_plot_rudyrudyrudy.py

File/Folder Name: **data**

File Contents and Use: All of the test files and different use cases for different parameters and sizes of the graphs

|  | <ul style="list-style-type: none"> <li>• General operation of code (for each subproject):       <p>Backtracking: I used a depth-first search algorithm to find a Hamiltonian cycle. First sorts the vertices and chooses the smallest as the start. Then builds the adjacency list using tuples. Then recursion depth-first search to add unvisited neighbors to the path, mark it visited, and continue. Then it backtracks and pops visited neighbors. When the path length equals the number of vertices it checks if the last vertex connects back to the start, if it does keep the cycle. IF a cycle was found, build the Hamiltonian path and print the return values.</p> <p><b>Brute Force</b></p> <ul style="list-style-type: none"> <li>- I read in the CSV file and put it into a vertex list and adjacency dictionary</li> <li>- Ran through to find all possible ways to make the cycle with the vertices</li> <li>- Through each of these, made a verifying function to check that the current pair did have an edge</li> <li>- This is also where the weight was calculated</li> <li>- Then kept track of the current best cycle option (accounting for the weight)</li> <li>- Returned the best cycle and weight, then calculated the time for how long each cycle took</li> <li>- Made an output CSV file for the weight, time, and exact cycle</li> </ul> <p>That was the original code ^ but then we had to re-work it and implement it into the test functions once we forked and cloned the github repo for the submission. This is because we had to match the function parameters, return values, and data structures. But we basically kept out code all the same, just adjusted it to match so it would run correctly.</p> <ul style="list-style-type: none"> <li>- Since it was already passed into vertices and edges, I just converted this into an adjacency list. Then sorting them and labeling the start vertex. Then used itertools to generate the permutations and test all the ordering and verify that there is an edge and if the last one connects back to the start vertex.</li> </ul> </li> </ul> |

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | <ul style="list-style-type: none"> <li>What test cases you used/added, why you used them, what did they tell you about the correctness of your code?<br/> <b>Backtracking:</b> I began with a 3-vertex triangle to confirm the solver was functioning correctly. I then tested larger graphs, 6-vertex, 7-vertex (no cycle), an 8-vertex graph with no cycle, an 8-vertex graph with a cycle, a 10-vertex graph, and finally a 12-vertex graph. The smaller graphs confirmed that the algorithm produced the correct cycle or correctly identified when no cycle existed. The larger graphs demonstrated how runtime increases with the number of vertices, which aligns with the exponential worst-case complexity of backtracking.<br/> <b>Brute Force:</b> Pretty much the same test files for each. Had a 3 vertex triangle, 6 vertex, 7 vertex (but with no cycle), 8, 9, 10, and 12 vertex graphs. The larger graphs were used to show how it is an exponential growth. This variety of graphs showed that the brute force works for both types of graphs and the run time increases pretty quickly.</li> </ul>                                                                                                                                                                                                                                                                             |
|    | <ul style="list-style-type: none"> <li>How did you manage the code development?<br/> <b>Backtracking:</b> I implemented easier functions to tackle first, like edge_weight and edge_exists. I struggled with recursion so I wanted to have enough time to work on it so I did that next. Next I added in small text graphs to verify minimum correctness before moving on. Then added the full graph file for the project. I then looked at google images to find Hamiltonian graphs to add into as test cases. Finally adding the timing measurement and printing outputs.<br/><br/> <b>Brute Force:</b> <ul style="list-style-type: none"> <li>- Worked slowly and tested almost line by line or function by function</li> <li>- First just made sure I could read the graphs and any csv files I was importing</li> <li>- Then started implementing the way to cycle through all of the different options for a cycle/path</li> <li>- Implemented a verifier to triple check that each pair of vertices did in fact have an edge between them</li> <li>- Once getting good results and I could verify with my own knowledge and reading the outputs, I decided to try implementing actual visuals to display</li> <li>- I just created separate python files to try not to mess with the main file. This is where I did the timing, plotting, and creating the visuals.</li> </ul> </li> </ul> |
| 13 | <p>Detailed discussion of results:</p> <p><b>Backtracking:</b> The runtime increased as the number of vertices increased. After running all graph files, I created an Excel scatter plot of runtime vs. <math> v </math>. Green markers were used for graphs where a Hamiltonian cycle was found, and red markers were used when no cycle existed. The resulting plot showed a noticeable upward trend as <math> v </math> increased, showing the exponential</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|    | <p>growth characteristic of backtracking approaches to NP-hard problems like the Hamiltonian cycle problem. This confirmed that the solver behaves as expected.</p> <p><b>Brute Force:</b></p> <ul style="list-style-type: none"> <li>- For the smaller size graphs (like 3-6) the code ran pretty fast (~0.0000195), but as we got up to about 8-12 vertices, it definitely started slowing down.</li> <li>- The 12 vertex graph took ~17 seconds, which really does show that exponential growth</li> <li>- For an example of no hamiltonian cycle, we used the 7 vertex graph</li> <li>- All the cycles for the complete and solvable graphs were also able to be outputted to a visual so we can see the actual path/cycle</li> </ul>                                   |
| 14 | <p>How team was organized:</p> <p>Katherine: In charge of the backtracking code, test graph files for backtracking, and collecting timing data for each test graph file</p> <p>Julia: In charge of the brute force algorithm, test files, the timing script, produces a “result” timing csv file and plot, as well as creating some visuals for all the graph cycles. Helped put together the readme file.</p>                                                                                                                                                                                                                                                                                                                                                              |
| 15 | <p>What might you do differently if you did the project again?</p> <p>Katherine: I would try to explore other algorithms that could be useful instead of using depth-first search. I wanted to stick with algorithms I was familiar with so I only looked at doing depth-first, breadth-first, or Dykstra's for potential options to solve the problem.</p> <p>Julia: I would definitely try more strategies to cut down on the timing. Obviously if I had more time, I could try to write up and learn a few more algorithms and compare the results, but I tried to just stick with what I was comfortable with. Also, I would maybe try to look at more libraries within Python. I am sure there are a few out there that would definitely help out with efficiency.</p> |
| 16 | <p>Any additional material:</p> <p><b>Graph Visual Tool</b></p> <ul style="list-style-type: none"> <li>- Separate plotting script</li> <li>- Draws out each test graph with the vertices on an approximate circle, and also the cycle lines (if it exists)</li> <li>- Outputted this into a PNG that automatically saves into the local folder I was connected to through VSCode</li> </ul> <p>Automated the process of reading the input graph files</p> <ul style="list-style-type: none"> <li>- Looked up how sort of use regex/search for specific pathnames in python</li> <li>- Came across the glob library (pattern matching)</li> </ul>                                                                                                                            |

- I think this would be helpful for future projects because it definitely speeds up the process of having to constantly upload/input the file names when testing (I am sure all the other coders in the class think this is light work, but I thought it was cool)
